ON DIRECT METHODS FOR SOLVING POISSON'S EQUATIONS*

B. L. BUZBEE,† G. H. GOLUB‡ AND C. W. NIELSON†

Abstract. Some efficient and accurate direct methods are developed for solving certain elliptic partial difference equations over a rectangle with Dirichlet, Neumann or periodic boundary conditions. Generalizations to higher dimensions and to L-shaped regions are included.

1. Introduction. In many physical applications, one must solve an $N \times N$ system of linear algebraic equations,

$$Mx = y,$$

where $M$ arises from a finite difference approximation to an elliptic partial differential equation. For this reason, the matrix $M$ is sparse and the nonzero elements occur very regularly. As an example, let

$$M = \begin{bmatrix} I & F \\ FT & I \end{bmatrix},$$

and partition $x$ and $y$ to conform with $M$. If one can interchange both the rows and the columns of a matrix so that it has the form $(M - I)$, the matrix is said to be two-cyclic [12]. Expanding (1.1), we have

$$x_1 + Fx_2 = y_1,$$
$$FTx_1 + x_2 = y_2.$$

Multiplying the first equation by $-FT$ and adding, we have

$$(I - FTF)x_2 = y_2 - FTy_1.$$

By this simple device, we have reduced the number of equations. If $(I - FTF)$ is also two-cyclic, we can again eliminate a number of the variables and continue until the resulting matrix is no longer two-cyclic. In fact, $F$ has block structure in many applications, and one has the freedom to specify the number of blocks in it. In these cases, a proper choice of the number of blocks may enable the reduction process to continue until the final $(I - FTF)$ has block dimension one; the reduction methods to be developed impose such a condition.

Direct methods for solving (1.1) are attractive since in theory they yield the exact solution to the difference equation, whereas commonly used methods seek to approximate the solution by iterative procedures [12]. Based on a suggestion of one of the authors, Hockney [8] has devised an efficient direct method which uses the reduction process. Also Buneman [2] recently developed an efficient direct method for solving the reduced system of equations. Since these methods offer considerable economy over older techniques [5], the purpose of

this paper is to present a unified mathematical development and generalization of them. Additional generalizations are given by George [6].

In § 2 we develop the method of matrix decomposition or discrete separation of variables. In § 3 we develop the block-cyclic reduction process and techniques for solving the reduced systems. In §§ 4, 5 and 6 we apply the results of §§ 2 and 3 to Poisson’s equation on a rectangle with Dirichlet, Neumann and periodic boundary conditions, respectively. Section 7 extends the results of §§ 4, 5 and 6 to higher dimensions; § 8 extends §§ 2 and 3 to other applications; § 9 extends §§ 2 and 3 to “L-shaped” regions. In § 10, we show that straightforward applications of the results of § 3 can result in severe roundoff error in many applications of interest. In § 11 we develop the Buneman algorithms, which are mathematically equivalent to the reduction process of § 3, but are not subject to severe roundoff. In § 11 we apply the Buneman algorithm to Poisson’s equation with Dirichlet, Neumann and periodic boundaries. Finally, in § 12 we show the stability of the Buneman algorithms.

2. Matrix decomposition. Consider the system of equations

\[ Mx = y, \]

where \( M \) is an \( N \times N \) real symmetric matrix of block tridiagonal form.

\[ M = \begin{bmatrix}
A & T \\
T & A \\
& & . \\
& & & & . \\
& & & & & & .
\end{bmatrix}, \]

The matrices \( A \) and \( T \) are \( p \times p \) symmetric matrices, and we assume that \( AT = TA \). Such a situation arises for those problems that can be handled by the classical separation-of-variables technique. Indeed, the methods we discuss amount to an efficient computer implementation of the idea of separation of variables carried out on a discretized model of the elliptic differential equation. Since \( A \) and \( T \) commute and are symmetric, it is well known [1] that there exists an orthogonal matrix \( Q \) such that

\[ Q^T AQ = \Lambda, \quad Q^T TQ = \Omega, \]

and \( \Lambda \) and \( \Omega \) are real diagonal matrices. The matrix \( Q \) is the set of eigenvectors of \( A \) and \( T \), and \( \Lambda \) and \( \Omega \) are the diagonal matrices of eigenvalues of \( A \) and \( T \), respectively.

To conform with the matrix \( M \), we write the vectors \( x \) and \( y \) in partitioned form.

\[ x = \begin{bmatrix} x_1 \\ x_2 \\ \vdots \\ x_q \end{bmatrix}, \quad y = \begin{bmatrix} y_1 \\ y_2 \\ \vdots \\ y_q \end{bmatrix}. \]
Furthermore, it is quite natural to write

\[ \mathbf{x}_j = \begin{bmatrix} x_{1j} \\ x_{2j} \\ \vdots \\ x_{pj} \end{bmatrix}, \quad \mathbf{y}_j = \begin{bmatrix} y_{1j} \\ y_{2j} \\ \vdots \\ y_{pj} \end{bmatrix}. \]  
(2.4)

System (2.2) may be written

\begin{align*}
(2.5a) & \quad A\mathbf{x}_1 + T\mathbf{x}_2 = \mathbf{y}_1, \\
(2.5b) & \quad T\mathbf{x}_{j-1} + A\mathbf{x}_j + T\mathbf{x}_{j+1} = \mathbf{y}_j, \quad j = 2, 3, \ldots, q - 1, \\
(2.5c) & \quad T\mathbf{x}_{q-1} + A\mathbf{x}_q = \mathbf{y}_q.
\end{align*}

Using (2.3), this becomes

\begin{align*}
\Lambda\mathbf{x}_1 + \Omega\mathbf{x}_2 = \mathbf{y}_1, \\
\Omega\mathbf{x}_{j-1} + \Lambda\mathbf{x}_j + \Omega\mathbf{x}_{j+1} = \mathbf{y}_j, \quad j = 2, 3, \ldots, q - 1, \\
\Omega\mathbf{x}_{q-1} + \Lambda\mathbf{x}_q = \mathbf{y}_q,
\end{align*}
(2.6)

where

\[ \mathbf{y}_j = Q^T \mathbf{x}_j, \quad \bar{\mathbf{y}}_j = Q^T \mathbf{y}_j. \]

The components of \( \mathbf{x}_j \) and \( \mathbf{y}_j \) are labeled as in (2.4). Then (2.6) may be rewritten for \( i = 1, 2, \ldots, p \),

\begin{align*}
\lambda_i \bar{x}_{i1} + \omega_i \bar{x}_{i2} = \bar{y}_{i1}, \\
\omega_i \bar{x}_{ij-1} + \lambda_i \bar{x}_{ij} + \omega_i \bar{x}_{ij+1} = \bar{y}_{ij}, \quad j = 2, \ldots, q - 1, \\
\omega_i \bar{x}_{iq-1} + \lambda_i \bar{x}_{iq} = \bar{y}_{iq}.
\end{align*}
(2.7)

Now let us write

\[ \Gamma_i = \begin{bmatrix} \lambda_i & \omega_i \\ \omega_i & \lambda_i \\ \vdots & \vdots & \ddots & \vdots \\ \omega_i & \lambda_i \end{bmatrix} \]

\[ \begin{bmatrix} \bar{x}_{i1} \\ \bar{x}_{i2} \\ \vdots \\ \bar{x}_{iq} \end{bmatrix}, \quad \begin{bmatrix} \bar{y}_{i1} \\ \bar{y}_{i2} \\ \vdots \\ \bar{y}_{iq} \end{bmatrix}. \]
so that (2.7) is equivalent to the system of equations

\[(2.8) \quad \Gamma_i \hat{x}_i = \hat{y}_i.\]

Thus, the vector \(\hat{x}_i\) satisfies a symmetric tridiagonal system of equations that has a constant diagonal element and a constant super- and subdiagonal element. After (2.8) has been solved, it is possible to solve for \(x_j = Q\hat{x}_j\). Thus the algorithm proceeds as follows:

(i) Compute or determine the eigenvectors of \(A\) and the eigenvalues of \(A\) and \(T\).
(ii) Compute \(\bar{y}_j = Q^T y_j, j = 1, 2, \ldots, q\).
(iii) Solve \(\Gamma_i \hat{x}_i = \hat{y}_i, i = 1, 2, \ldots, p\).
(iv) Compute \(x_j = Q \hat{x}_j, j = 1, 2, \ldots, q\).

Hockney [8] has carefully analyzed this algorithm for solving Poisson’s equation in a square. He has taken advantage of the fact that, in this case, the matrix \(Q\) is known and that one can use the fast Fourier transform [4] to perform steps (ii) and (iv). Shintani [11] has given methods for solving for the eigenvalues and eigenvectors in a number of special cases.

\(A\) and \(T\) need not commute. Assume that \(T\) is positive definite and symmetric. It is well known [1] that there is a matrix \(P\) such that

\[(2.9) \quad T = PP^T, \quad A = P \Delta P^T,\]

where \(\Delta\) is the diagonal matrix of eigenvalues of \(T^{-1}A\) and \(P^{-T}\) is the matrix of eigenvectors of \(T^{-1}A\). Thus, using (2.9), we modify the algorithm as follows:

(i) Compute or determine the eigenvalues and eigenvectors of \(T^{-1}A\).
(ii) Compute \(\bar{y}_j = P^{-1} y_j\).
(iii) Solve \(\Gamma_i \hat{x}_i = \hat{y}_i\), where

\[
\Gamma_i = \begin{bmatrix}
\delta_i & 1 & & \\
1 & \delta_i & & \\
& \ddots & \ddots & \\
& & 1 & \\
& & & 1 & \delta_i \\
\end{bmatrix}
\]

(iv) Compute \(x_j = P^{-T} \hat{x}_j\).

Of course, one should avoid computing \(T^{-1}A\), because this would destroy the sparseness of the matrices. Golub et al [7] has proposed an algorithm for solving \(Au = \delta Tu\) when \(A\) and \(T\) are sparse.

3. Block-cyclic reduction. In §2 we gave a method for which one had to know the eigenvalues and eigenvectors of some matrix. We now give a more direct method for solving the system of (2.1).

We assume again that \(A\) and \(T\) are symmetric and that \(A\) and \(T\) commute. Furthermore, we assume that \(q = m - 1\) and \(m = 2^{k+1}\), where \(k\) is some positive
integer. Let us rewrite (2.5b) as follows:

\[
\begin{align*}
T x_{j-2} + A x_{j-1} + T x_j &= y_{j-1}, \\
T x_{j-1} + A x_j + T x_{j+1} &= y_j, \\
T x_j + A x_{j+1} + T x_{j+2} &= y_{j+1}.
\end{align*}
\]

Multiplying the first and third equation by \(T\), the second equation by \(-A\) and adding, we have

\[
T^2 x_{j-2} + (2T^2 - A^2) x_j + T^2 x_{j+2} = Ty_{j-1} - Ay_j + Ty_{j+1}.
\]

Thus, if \(j\) is even, the new system of equations involves \(x_j\)'s with even indices. Similar equations hold for \(x_2\) and \(x_{m-2}\). The process of reducing the equations in this fashion is known as cyclic reduction. Then (2.1) may be written as the following equivalent system:

\[
\begin{bmatrix}
(2T^2 - A^2) & T^2 \\
T^2 & (2T^2 - A^2) \\
0 & 0 \\
\end{bmatrix}
\begin{bmatrix}
x_2 \\
x_4 \\
\vdots \\
x_{m-2}
\end{bmatrix}
= \begin{bmatrix}
Ty_1 + Ty_3 - Ay_2 \\
Ty_3 + Ty_5 - Ay_4 \\
\vdots \\
Ty_{m-1} + Ty_{m-3} - Ay_{m-2}
\end{bmatrix}
\]

(3.1)

and

\[
\begin{bmatrix}
A & 0 & 0 \\
0 & A & 0 \\
0 & 0 & A
\end{bmatrix}
\begin{bmatrix}
x_1 \\
x_3 \\
x_{m-1}
\end{bmatrix}
= \begin{bmatrix}
y_1 - Tx_2 \\
y_3 - Tx_2 - Tx_4 \\
\vdots \\
y_{m-1} - Tx_{m-2}
\end{bmatrix}
\]

(3.2)

Since \(m = 2^k + 1\) and the new system of (3.1) involves \(x_j\)'s with even indices, the block dimension of the new system of equations is \(2^k - 1\). Note that once (3.1) is solved, it is easy to solve for the \(x_j\)'s with odd indices, as evidenced by (3.2). We shall refer to the system of (3.2) as the eliminated equations.

Also, note that the algorithm of §2 may be applied to system (3.1). Since \(A\) and \(T\) commute, the matrix \((2T^2 - A^2)\) has the same set of eigenvectors as \(A\) and \(T\). Also, if

\[
\lambda(A) = \lambda_i, \quad \lambda(T) = \omega_i,
\]

\[
\lambda(2T^2 - A^2) = 2\omega_i^2 - \lambda_i^2 \quad \text{for } i = 1, 2, \ldots, m - 1.
\]

Hockney [8] has advocated this procedure.
Since system (3.1) is block tridiagonal and of the form of (2.2), we can apply the reduction repeatedly until we have one block. However, as noted above, we can stop the process after any step and use the methods of § 2 to solve the resulting equations.

To define the procedure recursively, let

\[ A^{(0)} = A, \quad T^{(0)} = T; \quad y_j^{(0)} = y_j, \quad j = 1, 2, \ldots, m - 1. \]

Then for \( r = 0, 1, \ldots, k \),

\[ A^{(r+1)} = 2(T^{(r)})^2 - (A^{(r)})^2, \]
\[ T^{(r+1)} = (T^{(r)})^2, \]
\[ y_j^{(r+1)} = T^{(r)}(y_{j-2r}^{(r)} + y_{j+2r}^{(r)}) - A^{(r)}y_j^{(r)}. \]

(3.3)

At each stage, we have a new system of equations

\[ M^{(r)}z^{(r)} = f^{(r)} \]

(3.4)

to solve, where

\[ M^{(r)} = \begin{bmatrix}
A^{(r)} & T^{(r)} & & 0 \\
T^{(r)} & A^{(r)} & \ddots & \\
& \ddots & \ddots & T^{(r)} \\
0 & & \ddots & A^{(r)}
\end{bmatrix}, \]

\[ z^{(r)} = \begin{bmatrix}
x_{2r} \\
x_{2r+1} \\
\vdots \\
x_{j-2r} \\
\vdots
\end{bmatrix}, \quad f^{(r)} = \begin{bmatrix}
y_{2r}^{(r)} \\
y_{2r+1}^{(r)} \\
\vdots \\
y_{j-2r}^{(r)} \\
\vdots
\end{bmatrix}. \]

The eliminated equations are the solution of the block diagonal system

\[ (3.5) \quad N^{(r)}w^{(r)} = g^{(r)}, \]

where

\[ N^{(r)} = \begin{bmatrix}
A^{(r-1)} & 0 & 0 \\
0 & A^{(r-1)} & \ddots \\
& \ddots & \ddots & 0 \\
0 & & \ddots & A^{(r-1)}
\end{bmatrix}, \]

\[ N^{(r)} = \begin{bmatrix}
A^{(r-1)} & 0 & 0 \\
0 & A^{(r-1)} & \ddots \\
& \ddots & \ddots & 0 \\
0 & & \ddots & A^{(r-1)}
\end{bmatrix}, \]
We can use the methods of § 2 to solve the system \( M^{(r)} z^{(r)} = f^{(r)} \), or we can proceed to compute \( M^{(r+1)} \) and eliminate half of the unknowns. After \( k \) steps, we must solve the system of equations

\[
A^{(k)} x^{(k)} = y^{(k)}.
\]

In either case, we must solve (3.5) to find the eliminated unknowns, just as in (3.2). This can be done by

1. direct solution,
2. eigenvalue-eigenvector factorization, or
3. polynomial factorization.

The direct solution is attractive when \( k \) is small. One can form the powers of \( A \) and \( T \) quite easily and solve the resulting equations by Gaussian elimination. Thus, if \( k = 1 \), and \( A \) and \( T \) are tridiagonal matrices, \( A^{(1)} \) is a five diagonal matrix, and for such band matrices it is easy to solve the resulting system of equations.

It is possible to compute the eigenvalue-eigenvector decomposition of \( A^{(r)} \) and \( T^{(r)} \). Since \( A^{(0)} = Q \Lambda Q^T \) and \( T^{(0)} = Q \Omega Q^T \), we may write

\[
A^{(r)} = Q \Lambda^{(r)} Q^T \quad \text{and} \quad T^{(r)} = Q \Omega^{(r)} Q^T.
\]

From (3.3), it follows that

\[
\Lambda^{(r+1)} = 2(\Omega^{(r)})^2 - (\Lambda^{(r)})^2,
\]

\[
\Omega^{(r+1)} = (\Omega^{(r)})^2.
\]

Thus the eigenvalues of \( A^{(r)} \) and \( T^{(r)} \) can be generated by the simple rule

\[
\lambda_i^{(r+1)} = 2(\omega_i^{(r)})^2 - (\lambda_i^{(r)})^2, \quad \lambda_i^{(0)} = \lambda_i, \quad \omega_i^{(r+1)} = 2(\omega_i^{(r)})^2, \quad \omega_i^{(0)} = \omega_i, \quad i = 1, 2, \ldots, m - 1.
\]

Hence, the methods of § 2 can easily be applied to solving the system \( M^{(r)} z^{(r)} = f^{(r)} \) and \( N^{(r)} w^{(r)} = g^{(r)} \). Hockney [9] has described this algorithm as the FACR(1) algorithm where \( l \) refers to the number of cyclic reductions performed.
From (3.1), we note that $A^{(1)}$ is a polynomial of degree 2 in $A$ and $T$. By induction, it is easy to show that $A^{(r)}$ is a polynomial of degree $2^r$ in the matrices $A$ and $T$, so that

$$A^{(r)} = \sum_{j=0}^{2r-1} c_{2j}^{(r)} A^{2j} T^{2^r - 2j} \equiv P_{2r}(A, T).$$

We shall proceed to determine the linear factors of $P_{2r}(A, T)$.

Let

$$p_{2r}(a, t) = \sum_{j=0}^{2r-1} c_{2j}^{(r)} a^{2j} t^{2^r - 2j}, \quad c_{2r}^{(r)} = -1.$$  

For $t \neq 0$, we make the substitution

$$a/t = -2 \cos \theta.$$  

From (3.3), we note that

$$p_{2r+1}(a, t) = 2t^{2r+1} - (p_{2r}(a, t))^2.$$  

It is then easy to verify, using (3.7) and (3.8), that

$$p_{2r}(a, t) = -2t^{2^r} \cos 2^r \theta,$$

and, consequently,

$$p_{2r}(a, t) = 0 \quad \text{when } a/(2t) = -\cos \left(\frac{2j - 1}{2^r + 1}\right) \pi \quad \text{for } j = 1, 2, \ldots, 2^r.$$

Thus, we may write

$$p_{2r}(a, t) = -\prod_{j=1}^{2r} \left[ a + 2t \cos \left(\frac{2j - 1}{2^r + 1}\right) \pi \right]$$

and hence

$$A^{(r)} = -\prod_{j=1}^{2r} (A + 2 \cos \theta_j^{(r)} T),$$

where $\theta_j^{(r)} = (2j - 1)\pi/2^r + 1$.

Let us write

$$G_j^{(k)} = A + 2 \cos \theta_j^{(k)} T.$$

Then, to solve (3.6), we set $z_1 = -y_2^{(k)}$ and repeatedly solve

$$G_j^{(k)} z_{j+1} = z_j \quad \text{for } j = 1, 2, \ldots, 2^k.$$  

Thus,

$$z_{2^k + 1} = x_{2^k}. $$
If $A$ and $T$ are of band structure, it is simple to solve (3.9). To determine the solution to the eliminated (3.5), a similar algorithm may be used with

$$A^{(r)} = - \prod_{j=1}^{2^r} G_j^{(r)}.$$  

The factorization for $A^{(r)}$ may also be used to compute $y^{(r+1)}_j$ in (3.3). It is possible, however, to take advantage of the recursive nature of the polynomials $p_{2^r}(a, t)$. Let

$$p_4(a, t) = -2t^2 \cos \theta,$$

where, again, for $t \neq 0, a/t = -2 \cos \theta$. Then a short manipulation shows that

$$p_s(a, t) = -ap_{s-1}(a, t) - t^2p_{s-2}(a, t), \quad s \geq 2.$$  
$$p_0(a, t) = -2, \quad p_1(a, t) = a.$$  

Therefore, to compute $A^{(r)}y^{(r)}_j$ as in (3.3), we compute the following sequence:

$$\eta_0 = 2y^{(r)}_j, \quad \eta_1 = Ay^{(r)}_j,$$  
$$\eta_s = -A\eta_{s-1} - T^2\eta_{s-2} \quad \text{for} \quad s = 2, 3, \ldots, 2^r.$$  

Thus,

$$\eta_{2^r} = P_{2^r}(A, T)y^{(r)}_j \equiv A^{(r)}y^{(r)}_j.$$  

We call this method the cyclic odd–even reduction and factorization (CORF) algorithm. In §10 we will show that the numerical calculation of $y^{(r)}_j$ in (3.3) is subject to severe rounding errors in many cases of interest. Consequently, numerical application of the results of this section must be accompanied by close attention to the results of §10. In fact, from a computational viewpoint, the CORF algorithm, as developed here, is virtually useless; however, the theoretical results of this section are necessary for the development of the stable, Buneman variants of CORF.

4. Poisson's equation with Dirichlet boundary conditions. It is instructive to apply the results of §3 to the solution of the finite difference approximation to Poisson's equation on a rectangle, $R$, with specified boundary values. Consider the equation

$$u_{xx} + u_{yy} = f(x, y) \quad \text{for} \quad (x, y) \in R,$$  
$$u(x, y) = g(x, y) \quad \text{for} \quad (x, y) \in \partial R.$$  

(Here $\partial R$ indicates the boundary of $R$.) We assume that the reader is familiar with the general technique of imposing a mesh of discrete points onto $R$ and approximating (4.1). The equation $u_{xx} + u_{yy} = f(x, y)$ is approximated at $(x_i, y_j)$ by

$$\frac{v_{i-1,j} - 2v_{i,j} + v_{i+1,j}}{(\Delta x)^2} + \frac{v_{i,j-1} - 2v_{i,j} + v_{i,j+1}}{(\Delta y)^2} = f_{i,j},$$

$$1 \leq i \leq n - 1, \quad 1 \leq j \leq m - 1,$$
with
\[ v_{0,j} = g_{0,j}, \quad v_{n,j} = g_{n,j}, \quad 1 \leq j \leq m - 1, \]
and
\[ v_{i,0} = g_{i,0}, \quad v_{i,m} = g_{i,m}, \quad 1 \leq i \leq n - 1. \]
Then \( v_{ij} \) is an approximation to \( u(x_i, y_j) \), and \( f_{ij} = f(x_i, y_j), g_{ij} = g(x_i, y_j) \).

Hereafter, we assume that \( m = 2k + 1 \).

When \( u(x, y) \) is specified on the boundary, we have the Dirichlet boundary condition. For simplicity, we shall assume hereafter that \( \Delta x = \Delta y \). This leads to the system of equations

\[
M_D v = y,
\]
where \( M_D \) is of the form of (2.1) with
\[
A = \begin{bmatrix}
-4 & 1 & 0 \\
1 & -4 & 1 \\
& & \ddots & \ddots \\
& & & 1 \\
0 & & & & 1 \\
1 & & & & -4 \\
\end{bmatrix}_{(n-1) \times (n-1)}
\]
and
\[
T = I_{n-1}.
\]
The matrix \( I_{n-1} \) indicates the identity matrix of order \((n - 1)\). \( A \) and \( T \) are symmetric, and commute, and thus, the results of §§ 2 and 3 are applicable. In addition, since \( A \) is tridiagonal, the use of the factorization (3.10) is greatly simplified.

5. **Neumann boundary conditions.** When the normal derivative, \( \partial u / \partial n \), is specified on the boundary, we have the Neumann boundary condition. Assume that
\[
\frac{\partial u}{\partial n} = g(x, y) \quad \text{when} \quad (x, y) \in R.
\]
We make the approximation
\[
\frac{\partial u}{\partial x} \approx \frac{u(x + \Delta x, y) - u(x - \Delta x, y)}{2\Delta x}, \quad \frac{\partial u}{\partial y} \approx \frac{u(x, y + \Delta y) - u(x, y - \Delta y)}{2\Delta y}.
\]
This approximation leads to the matrix equation
\[
M_N v = y,
\]
where \( M_N \) is of the form
\[
\begin{bmatrix}
A & 2T & 0 \\
T & A & T \\
& & \ddots & \ddots \\
& & & 1 & T \\
0 & & & & 2T & A
\end{bmatrix}
\]
Here,

\[
A = \begin{bmatrix}
-4 & 2 & 0 \\
1 & -4 & 1 \\
& & \ddots \\
0 & 1 & -4 \\
& & & 2 & -4 \\
\end{bmatrix}, \quad T = I_{n+1}.
\]

Again \(A\) and \(T\) commute, but \(M\) no longer has the structure given by (2.2). Therefore it is necessary to modify the algorithm of § 3.

From (5.1), we see that

\[
Av_0 + 2Tv_1 = y_0, \\
Tv_{j-1} + Av_j + Tv_{j+1} = y_j, \quad j = 1, 2, \ldots, m - 1, \\
2Tv_{m-1} + Av_m = y_m.
\]

Performing the cyclic reduction as in § 3, we have

\[
(2T^2 - A^2)v_0 + 2Tv_2 = -Ay_0 + 2Ty_1, \\
T^2v_{j-2} + (2T^2 - A^2)v_j + T^2v_{j+2} = T(y_{j-1} + y_{j+1}) - Ay_j, \quad j = 2, 4, \ldots, m - 2, \\
2Tv_{m-2} + (2T^2 - A^2)v_m = 2Ty_{m-1} - Ay_m.
\]

The similarity of (5.2) to (3.1) should now be evident. Since (5.2) is of block dimension \(2^k + 1\), after \(k\) steps we have the system

\[
\begin{bmatrix}
A^{(k)} & 2T^{(k)} & 0 \\
T^{(k)} & A^{(k)} & T^{(k)} \\
0 & 2T^{(k)} & A^{(k)}
\end{bmatrix}
\begin{bmatrix}
v_0 \\
v_{2^k} \\
v_{2^k+1}
\end{bmatrix}
=
\begin{bmatrix}
y_0^{(k)} \\
y_{2^k}^{(k)} \\
y_{2^k+1}^{(k)}
\end{bmatrix},
\]

and a final reduction yields

\[
[4(T^{(k)})^2 - (A^{(k)})^2]y_{2^k} = T(y_0^{(k)} + y_{2^k+1}^{(k)}) - Ay_{2^k}^{(k)}.
\]

Equation (5.4) is equivalent to writing

\[
P^{(N)}_{2^k}(A, T)v_{2^k} = y_{2^k+1}^{(k)},
\]

where \(P^{(N)}_{2^k}(A, T)\) is again a polynomial of degree \(2^k+1\) in \(A\) and \(T\). Note that from (3.8),

\[
p^{(N)}_{2^k}(a, t) = 2t^{2^r} - [p^{(N)}_{2^k}(a, t)]^2, \quad r = 0, 1, \ldots, k - 1,
\]

and from (5.4),

\[
p^{(N)}_{2^k}(a, t) = 4t^{2^k+1} - [p^{(N)}_{2^k}(a, t)]^2.
\]

Therefore, since \(p_{2^k}(a, t) = -2t^{2^k} \cos 2^k \theta\),

\[
p^{(N)}_{2^k}(a, t) = (2t^{2^k} \sin 2^k \theta)^2.
\]
and, thus,

\[ p_{2k}^{(N)}(a, t) = 0 \quad \text{when} \quad a/2t = -\cos \frac{j\pi}{2^k} \quad \text{for} \quad j = 1, 2, \ldots, 2^k. \]

Consequently, we may rewrite (5.5) as

\[ \prod_{j=1}^{2^k+1} \left[ A + 2 \cos \theta_j^{(k+1)} T \right] v_{2k} = -\gamma_{2k}^{(k+1)}, \]

where \( \theta_j^{(k+1)} = j\pi/2^k \). Again, \( v_{2k} \) is determined by solving \( 2^k+1 \) tridiagonal systems. The other components of \( v \) are solved in the manner indicated in § 3.

Note that the application of matrix decomposition to this problem only requires the modification of the tridiagonal matrices \( \Gamma_j \) in (2.8); i.e., the first superdiagonal and the last subdiagonal elements must be \( 2\omega_j \).

It is well known that the solution to Poisson’s equation is not unique in this case. Therefore, we would expect the finite difference approximation to be singular. This is easy to verify by noting that

\[ M_N e = 0, \]

where \( e^T = (1, 1, \ldots, 1) \). In addition, one of the systems of the tridiagonal matrices in (5.6) is also singular. On a uniform mesh, the eigenvalues of \( (A + 2 \cos \theta_j T) \) satisfy the equation

\[ \lambda_j (A + 2 \cos \theta_j T) = 4 - 2 \cos \left( \frac{l\pi}{n} \right) + 2 \cos \left( \frac{j\pi}{2^k} \right), \]

\[ l = 0, 1, 2, \ldots, n, \quad j = 1, 2, \ldots, 2^k. \]

Then \( \lambda_0 = 0 \) when \( j = 2^k \). Similarly, one can show that \( \Gamma_0 \) of matrix decomposition is singular. Normally, the physics of the problem determines the coefficient of the homogeneous solution for the singular case.

6. Periodic boundary conditions. In this section, we shall consider the problem of solving the finite difference approximation to Poisson’s equation over a rectangle when

\[ u(x_0, y) = u(x_n, y), \]

\[ u(x, y_0) = u(x, y_n). \]

The periodic boundary conditions (6.1) lead to the matrix equation

\[ M_p v = y, \]
where

\[
M_p = \begin{bmatrix}
A & T & 0 & \cdots & 0 & T \\
T & A & T & \cdots & 0 \\
0 & \cdots & \cdots & \cdots & 0 \\
0 & \cdots & \cdots & \cdots & 0 \\
0 & \cdots & T & A & T \\
T & 0 & \cdots & 0 & T & A
\end{bmatrix}
\]

and

\[
A = \begin{bmatrix}
-4 & 1 & 0 & \cdots & 0 & 1 \\
1 & -4 & 1 & 0 & \cdots & 0 \\
0 & \cdots & \cdots & \cdots & 0 \\
0 & \cdots & \cdots & \cdots & 0 \\
0 & \cdots & 1 & -4 & 1 \\
1 & 0 & \cdots & 0 & 1 & -4
\end{bmatrix}_{n \times n}, \quad T = I_n.
\]

Note that \(M_p\) is "almost" an \(m\) block tridiagonal system and, similarly, \(A\) is "almost" an \(n \times n\) tridiagonal matrix. The cyclic reduction can again be performed on (6.2), and this leads to the reduced system

\[
(2T^2 - A^2)v_2 + T^2v_4 + T^2v_m = T(y_1 + y_3) - Ay_2, \quad j = 2, 4, \ldots, m - 2,
\]

\[
T^2v_{j-2} + (2T^2 - A^2)v_j + T^2v_{j+2} = T(y_{j-1} + y_{j+1}) - Ay_j, \quad j = 2, 4, \ldots, m - 2,
\]

\[
T^2v_2 + T^2v_{m-2} + (2T^2 - A^2)v_m = T(y_1 + y_{m-1}) - Ay_m.
\]

The similarity with the previous cases is again evident. Equation (6.3) has block dimension \(2^k\). After \((k - 1)\) reductions, we have

\[
M_p^{(k-1)} = \begin{bmatrix}
A^{(k-1)} & T^{(k-1)} & 0 & T^{(k-1)} \\
T^{(k-1)} & A^{(k-1)} & T^{(k-1)} & 0 \\
0 & T^{(k-1)} & A^{(k-1)} & T^{(k-1)} \\
T^{(k-1)} & 0 & T^{(k-1)} & A^{(k-1)}
\end{bmatrix}
\]

and finally, after \(k\) reductions,

\[
\begin{bmatrix}
A^{(k)} & 2T^{(k)} \\
2T^{(k)} & A^{(k)}
\end{bmatrix}
\begin{bmatrix}
v_{2^k} \\
v_{2^{k-1}+1}
\end{bmatrix}
= \begin{bmatrix}
y_{2^k}^{(k)} \\
y_{2^{k-1}+1}^{(k)}
\end{bmatrix}.
\]
From (6.4), the final equation becomes
\[ (4T^{(k)2} - A^{(k)2})v_{2k} = y_{2k}^{(k+1)}, \]
which is equivalent to
\[ P_{2k}^{(k)}(A, T)v_{2k} = y_{2k}^{(k+1)}. \]

The analysis of the factorization of \( P_{2k}^{(k)}(A, T) \) is identical to that of the Neumann case, including the fact that one of the factors of the polynomial must be singular.

Again, the application of matrix decomposition to (6.2) is straightforward; however, the resulting \( \Gamma_i \) matrices are no longer tridiagonal, since \( \omega_i \) appears in the \( (l, n) \) and \( (n, 1) \) elements. Standard algorithms for solving tridiagonal systems can be modified to solve these systems such that storage of the full \( n \times n \) matrix is avoided. As above, one of the \( \Gamma_i \) will be singular.

7. Higher-dimensional problems. It is not difficult to extend the applications given in §§ 4, 5 and 6 to higher-dimensional problems. We show this by a simple example. Consider Poisson's equation in three dimensions over the rectangle \( R \):
\[ u_{xx} + u_{yy} + u_{zz} = f(x, y, z), \quad (x, y, z) \in R, \]
\[ u(x, y, z) = g(x, y, z), \quad (x, y, z) \in \partial R. \]

Again, we assume that the mesh is uniform in each direction, so that
\[ x_{i+1} = x_i + \Delta x, \quad i = 0, 1, \ldots, n, \]
\[ y_{j+1} = y_j + \Delta y, \quad j = 0, 1, \ldots, m, \]
\[ z_{l+1} = z_l + \Delta z, \quad l = 0, 1, \ldots, p. \]

At the point \((x_i, y_j, z_l)\), we approximate \( u(x_i, y_j, z_l) \) by \( v_{i,j,l} \). Let
\[ \mathbf{w}_i = \begin{bmatrix} v_{1,i} \\ v_{2,i} \\ \vdots \\ v_{m-1,i} \end{bmatrix}, \quad \text{where} \quad \mathbf{v}_{j,l} = \begin{bmatrix} v_{1,j,l} \\ v_{2,j,l} \\ \vdots \\ v_{n-1,j,l} \end{bmatrix}. \]

Assume that the usual finite difference approximation is made to \( u_{zz} \) for fixed \((x, y, z)\), namely,
\[ u_{zz}(x, y, z) \approx \frac{u(x, y, z - \Delta z) - 2u(x, y, z) + u(x, y, z + \Delta z)}{(\Delta z)^2}. \]

It is then easy to verify that for \( l = 1, 2, \ldots, p - 1, \)
\[ \mathbf{w}_{l-1} + H\mathbf{w}_l + \mathbf{w}_{l+1} = \mathbf{f}_l, \]
where \( \mathbf{w}_0 \) and \( \mathbf{w}_p \) are prescribed by the initial conditions and \( \mathbf{f}_l \) is a function of the given data. Thus, again, we have a block tridiagonal matrix, and can use the previously developed methods. Note, also, that \( H \) is a block tridiagonal matrix so that one can solve any of the eliminated systems of equations by applying
the CORF algorithm repeatedly. Other boundary conditions can be handled in the manner prescribed in §§ 5 and 6.

8. Further applications. Consider the elliptic equation in self-adjoint form

\[ (\alpha(x)u_x)_x + (\beta(y)u_y)_y + u(x, y) = q(x, y), \quad (x, y) \in R, \]
\[ u(x, y) = g(x, y), \quad (x, y) \in \partial R. \]

(8.1)

Many equations can be transformed to this form. The usual five-point difference equation, when \( \Delta x = \Delta y \), leads to the following equation:

\[ -\alpha_{i+1/2}v_{i+1,j} - \alpha_{i-1/2}v_{i-1,j} - \beta_{j+1/2}v_{i,j+1} - \beta_{j-1/2}v_{i,j-1} + [\alpha_{i+1/2} + \alpha_{i-1/2} + \beta_{j+1/2} + \beta_{j-1/2} - (\Delta x)^2]v_{i,j} = -(\Delta x)^2 q_{i,j}, \]

where

\[ \alpha_{i \pm 1/2} = \alpha(x_i \pm \Delta x/2), \quad \beta_{j \pm 1/2} = \beta(y_j \pm \Delta y/2), \quad q_{i,j} = q(x_i, y_j), \]

If the equations are ordered with

\[
\begin{bmatrix}
  \mathbf{v}_1 \\
  \mathbf{v}_2 \\
  \vdots \\
  \mathbf{v}_{m-1}
\end{bmatrix}, \quad \begin{bmatrix}
  \mathbf{v}_{1,j} \\
  \mathbf{v}_{2,j} \\
  \vdots \\
  \mathbf{v}_{n-1,j}
\end{bmatrix},
\]

the linear system of equations \( M\mathbf{v} = \mathbf{d} \) will have the block form

\[
\begin{bmatrix}
  A_1 & T_1 & 0 \\
  T_1 & A_2 & T_2 \\
  & \ddots & \ddots \\
  0 & T_{m-2} & A_{m-1}
\end{bmatrix}
\begin{bmatrix}
  \mathbf{v}_1 \\
  \mathbf{v}_2 \\
  \vdots \\
  \mathbf{v}_{m-1}
\end{bmatrix} =
\begin{bmatrix}
  \mathbf{d}_1 \\
  \mathbf{d}_2 \\
  \vdots \\
  \mathbf{d}_{m-1}
\end{bmatrix}
\]

Here

\[
A_j = [\beta_{j+1/2} + \beta_{j-1/2} - (\Delta x)^2]I
\]

\[
\begin{array}{cccc}
\alpha_{1/2} + \alpha_{3/2} & -\alpha_{3/2} & & \\
-\alpha_{3/2} & \alpha_{3/2} + \alpha_{5/2} & -\alpha_{5/2} & \\
& \ddots & \ddots & \ddots \\
& & & -\alpha_{n-3/2} & -\alpha_{n-3/2} + \alpha_{n-1/2} & \\
\end{array}
\]

\[
\equiv \gamma_j I + C, \quad T_j = \beta_{j+1/2}I.
\]

Now suppose we have the decomposition

\[ Q^T C Q = \Phi, \]
where $Q^TQ = I$ and $\text{diag}(\Phi) = (\varphi_1, \varphi_2, \ldots, \varphi_{n-1})$. Thus,

$$\lambda_i(A_j) = \gamma_j + \varphi_i \quad (i = 1, 2, \ldots, n-1)$$

$$\equiv \lambda_{i,j}.$$  

As in § 2, we define

$$\mathbf{v}_j = Q^T\mathbf{v}_j, \quad \mathbf{d}_j = Q^T\mathbf{d}_j,$$

and after a suitable permutation we are led to the equations

$$\Gamma_i \mathbf{v}_i = \mathbf{d}_i, \quad i = 1, 2, \ldots, n-1,$$

where

$$\Gamma_i = \begin{bmatrix}
\lambda_{i,1} & \beta_{3/2} & 0 \\
\beta_{3/2} & \lambda_{i,2} & \beta_{5/2} \\
\vdots & \vdots & \ddots \\
0 & \beta_{m-3/2} & \beta_{m-3/2} & \lambda_{i,m-1}
\end{bmatrix},$$

$$\mathbf{v}_i = \begin{bmatrix}
\mathbf{v}_{i,1} \\
\mathbf{v}_{i,2} \\
\vdots \\
\mathbf{v}_{i,m-1}
\end{bmatrix}, \quad \mathbf{d}_i = \begin{bmatrix}
\mathbf{d}_{i,1} \\
\mathbf{d}_{i,2} \\
\vdots \\
\mathbf{d}_{i,m-1}
\end{bmatrix}.$$  

Thus, the vector $\mathbf{v}_i$ satisfies a symmetric tridiagonal system of equations. Again, once $\mathbf{v}_i$ is computed for all $i$, it is possible to compute $\mathbf{d}_i$.

Lynch et al. [10] have considered similar methods, but their algorithm requires more operations. Unfortunately, it does not seem possible to use the methods of § 3 on (8.2) in this situation.

Now we may write the equivalent to Poisson’s equation in two dimensions in cylindrical coordinates as follows:

$$(ru_r)_r + r^{-1}u_{\theta\theta} = s(r, \theta),$$

and

$$(ru_r)_r + ru_\theta\theta = t(r, z).$$

The matrix $A$ will still be tridiagonal, and $T$ will be a diagonal matrix with positive diagonal elements. We may make the transformation $\hat{\mathbf{v}}_j = T^{1/2} \mathbf{v}_j$, and are thus led to the equations

$$\hat{\mathbf{v}}_{j-1} + T^{-1/2}AT^{-1/2}\hat{\mathbf{v}}_j + \hat{\mathbf{d}}_{j+1} = T^{-1/2}\mathbf{d}_j.$$  

Thus, by ordering the equations correctly and by making a simple transformation, one can apply the cyclic reduction and the CORF algorithm to solve the finite difference approximation to Poisson’s equation in cylindrical coordinates.
Another situation in which the methods of §§ 2 and 3 are applicable is in using the nine-point formula to solve the finite difference approximation to Poisson’s equation in the rectangle. In this case, when \(\Delta x = \Delta y\),

\[
A = \begin{bmatrix}
-20 & 4 & 0 \\
4 & -20 & \ddots \\
0 & \ddots & \ddots & 4 \\
\end{bmatrix}_{(n-1) \times (n-1)}
\]

\[
T = \begin{bmatrix}
4 & 1 & 0 & \\
1 & 4 & \ddots & \\
0 & \ddots & \ddots & 1 \\
\end{bmatrix}_{(n-1) \times (n-1)}
\]

It is easy to verify that \(AT = TA\) and that the eigenvalues of \(A\) and \(T\) are

\[
\lambda_i(A) = -20 + 8 \cos \frac{i\pi}{n}, \quad i = 1, 2, \ldots, n-1,
\]

\[
\lambda_i(T) = 4 + 2 \cos \frac{i\pi}{n}, \quad i = 1, 2, \ldots, n-1.
\]

Because of the structure of \(A\) and \(T\), the fast Fourier transform may be employed when using the methods of § 2.

9. **Nonrectangular regions.** In many situations, one wishes to solve an elliptic equation over the region in Fig. 1.

![Fig. 1](image)

We shall assume that Dirichlet boundary conditions are given. When \(\Delta x\) is the same throughout the region, one has a matrix equation of the form

\[
\begin{bmatrix}
G & P \\
0 & 0
\end{bmatrix}
\begin{bmatrix}
x^{(1)} \\
x^{(2)}
\end{bmatrix}
\begin{bmatrix}
y^{(1)} \\
y^{(2)}
\end{bmatrix} = 0
\]

(9.1)
where

\[ G = \begin{bmatrix} A & T & 0 \\ T & A & \cdot \\ \cdot & \cdot & T \\ 0 & T & A \end{bmatrix}, \quad H = \begin{bmatrix} B & S & 0 \\ S & B & \cdot \\ \cdot & \cdot & S \\ 0 & S & B \end{bmatrix}. \]

Also, we write

\[ x^{(1)} = \begin{bmatrix} x_1^{(1)} \\ x_2^{(1)} \\ \vdots \\ x_r^{(1)} \end{bmatrix}, \quad x^{(2)} = \begin{bmatrix} x_1^{(2)} \\ x_2^{(2)} \\ \vdots \\ x_r^{(2)} \end{bmatrix}. \]

We assume again that \( AT = TA \) and \( BS = SB \).

From (9.1), we see that

\[ x^{(1)} = G^{-1} y^{(1)} - G^{-1} \begin{bmatrix} 0 \\ 0 \\ \vdots \\ P \end{bmatrix} x_1^{(2)}, \]

and

\[ x^{(2)} = H^{-1} y^{(2)} - H^{-1} \begin{bmatrix} P^T \\ 0 \\ \vdots \\ 0 \end{bmatrix} x_r^{(1)}. \]

Now let us write

\[ G z^{(1)} = y^{(1)}, \quad H z^{(2)} = y^{(2)}, \]

\[ GW^{(1)} = \begin{bmatrix} 0 \\ 0 \\ \vdots \\ P \end{bmatrix}, \quad HW^{(2)} = \begin{bmatrix} P^T \\ 0 \\ \vdots \\ 0 \end{bmatrix}. \]
Then as we partition the vectors $z^{(1)}$, $z^{(2)}$ and the matrices $W^{(1)}$ and $W^{(2)}$ as in (9.3), (9.4) and (9.5) become

\begin{align*}
  x^{(1)}_j &= z^{(1)}_j - W^{(1)} x^{(2)}_j, \quad j = 1, 2, \ldots, r, \\
  x^{(2)}_j &= z^{(2)}_j - W^{(2)} x^{(1)}_j, \quad j = 1, 2, \ldots, s.
\end{align*}

(9.8)

For (9.8), we have

\[
\begin{bmatrix}
  I & W^{(1)}_1 \\
  W^{(2)}_1 & I
\end{bmatrix}
\begin{bmatrix}
  x^{(1)}_r \\
  x^{(2)}_r
\end{bmatrix}
= \begin{bmatrix}
  z^{(1)}_r \\
  z^{(2)}_r
\end{bmatrix}.
\]

This system of equations is two-cyclic, so we may reduce the system to

\begin{equation}
(I - W^{(1)}_1 W^{(2)}_1) x^{(1)}_r = z^{(1)}_r - W^{(1)}_1 z^{(2)}_r.
\end{equation}

(9.9)

This system of equations can most easily be solved using Gaussian elimination. Once the two-cyclic system of (9.9) has been solved, all other components may be computed using (9.8) or by solving the system

\[
G x^{(1)} = y^{(1)} - x^{(2)}_r,
\]

\[
H x^{(2)} = y^{(2)} - x^{(1)}_r.
\]

If system (9.1) is to be solved for a number of different right-hand sides, it is best to save the LU decomposition of

\begin{equation}
(I - W^{(1)}_1 W^{(2)}_1).
\end{equation}

(9.10)

Thus, the algorithm proceeds as follows:

(i) Solve for $z^{(1)}_r$ and $z^{(2)}_r$ using the methods of § 2 or 3.

(ii) Solve for $W^{(1)}_1$ and $W^{(2)}_1$ using the methods of § 2 or 3.

(iii) Solve (9.9) using Gaussian elimination. Save the LU decomposition of (9.10).

(iv) Solve for the unknown components of $x^{(1)}$ and $x^{(2)}$. 
10. Accuracy of the CORF algorithm. As will be shown in §11, the CORF algorithm and the Buneman algorithms are mathematically identical. The difference between the methods lies in the way the right-hand side is calculated at each stage of the reduction. To the authors’ knowledge, this is the only direct method for solving linear equations in which the right-hand side of the equations plays an important role in the numerical solution of the equations. In this section, we show the difficulties encountered in using the CORF algorithm. In §13, we will prove the stability of the Buneman algorithms.

Recall from §3 that it is possible to compute \( A^{(r)}y^{(r)} \) by the following algorithm:

\[
\begin{align*}
\eta_0 &= -2y^{(r)}, & \eta_1 &= Ay^{(r)}, \\
\eta_s &= -A\eta_{s-1} - T^2\eta_{s-2}
\end{align*}
\]  

(10.1)

for \( s = 2, 3, \ldots, 2^r \), so that

\[ \eta_{2^r} = A^{(r)}y^{(r)}. \]

Because of roundoff error, one actually computes the sequence

\[
\begin{align*}
\tilde{\eta}_0 &= -2\tilde{y}^{(r)}, & \tilde{\eta}_1 &= \tilde{Ay}^{(r)} + \delta_0, \\
\tilde{\eta}_s &= -A\tilde{\eta}_{s-1} - T^2\tilde{\eta}_{s-2} + \delta_{s-1}, & s &= 2, \ldots, 2^r,
\end{align*}
\]  

(10.2)

where \( \delta_s \) is the perturbation induced by the roundoff error. Again, as in §2, we write

\[
A = Q\Lambda Q^T, \quad T = Q\Omega Q^T,
\]  

(10.3)

where \( Q \) is the set of orthonormalized eigenvectors of \( A \) and \( T \), and \( \Lambda \) and \( \Omega \) are the diagonal matrices of eigenvalues of \( A \) and \( T \), respectively. Thus, substituting (10.3) into (10.2), we have

\[
\begin{align*}
\tilde{\xi}_0 &= -2\tilde{y}, & \tilde{\xi}_1 &= -\frac{1}{2}\Lambda\tilde{\xi}_0 + \tau_0, \\
\tilde{\xi}_s &= -\Lambda\tilde{\xi}_{s-1} - \Omega^2\tilde{\xi}_{s-2} + \tau_{s-1},
\end{align*}
\]  

(10.4a)

\[
\begin{align*}
\tilde{\xi}_s &= -\Lambda\tilde{\xi}_{s-1} - \Omega^2\tilde{\xi}_{s-2} + \tau_{s-1},
\end{align*}
\]  

(10.4b)

where

\[
\tilde{y} = Q^T\tilde{y}^{(r)}, \quad \tilde{\xi}_s = Q^T\tilde{\xi}_s, \quad \tau_s = Q^T\delta_s.
\]
Because $\Lambda$ and $\Omega$ are diagonal, we may write an equation for each component of $\xi_s$; namely,

\( (10.5) \)

\[ \xi_{j,s+1} + \lambda_j \xi_{j,s} + \omega_j^2 \xi_{j,s-1} = \tau_{j,s}, \quad j = 1, 2, \ldots, p. \]

The solution of (10.5) can be given explicitly. Consider the characteristic equation

\[ \varphi(x) \equiv x^2 + \lambda_j x + \omega_j^2 = 0, \]

which has roots $\beta_j$ and $\gamma_j$; then

\[ (10.6a) \]

\[ \xi_{j,s} = \frac{\beta_j - \gamma_j}{\beta_j - \gamma_j} \xi_{j,1} - \frac{\beta_j^{s-1} - \gamma_j^{s-1}}{\beta_j - \gamma_j} \xi_{j,0} + \sum_{k=1}^{s-1} \frac{\beta_j^{s-k} - \gamma_j^{s-k}}{\beta_j - \gamma_j} \tau_{j,k} \quad \text{when } \beta_j \neq \gamma_j, \]

\[ (10.6b) \]

\[ = s\beta_j^{s-1}\xi_{j,1} - (s - 1)\beta_j^s\xi_{j,0} + \sum_{k=1}^{s-1} (s - k)\beta_j^{s-k-1}\tau_{j,k} \]

\[ \quad \text{when } \beta_j = \gamma_j. \]

Let

\[ -\frac{\lambda_j}{2\omega_j} = \cos \theta_j \quad \text{when } |\lambda_j/(2\omega_j)| \leq 1, \]

\[ = \cosh z_j \quad \text{when } |\lambda_j/(2\omega_j)| \geq 1. \]

Then using the initial conditions of (10.4a), we may write (10.6a) as

\[ (10.7a) \]

\[ \xi_{j,s} = -2\omega_j^s \cos (s\theta_j)\tilde{y}_j + \sum_{k=0}^{s-1} \omega_j^{s-k-1} \frac{\sin (s - k)\theta_j}{\sin \theta_j} \tau_{j,k} \]

\[ \quad \text{when } |\lambda_j/(2\omega_j)| \leq 1, \]

\[ = -2\omega_j^s \cosh (sz_j)\tilde{y}_j + \sum_{k=0}^{s-1} \omega_j^{s-k-1} \frac{\sinh (s - k)z_j}{\sinh z_j} \tau_{j,k} \]

\[ \quad \text{when } |\lambda_j/(2\omega_j)| \geq 1. \]

Note that

\[ (10.8) \]

\[ -2\omega_j^s \times \begin{cases} \cos s\theta_j \\ \cosh sz_j \end{cases} \equiv p_s(\lambda_j, \omega_j), \]

given in § 3. Thus

\[ (10.9) \]

\[ \mathbf{\hat{n}} = P_s(A, T) \mathbf{y}_j^{(0)} + \sum_{k=0}^{s-1} QS_{s-k}Q^T \delta_k, \]
where

$$\{S_m\}_{ij} = \omega_j^{m-1} \times \begin{cases} \sin m\theta_j \\ \sin \theta_j \end{cases} \quad \text{when} \quad |\lambda_j / (2\omega_j)| \leq 1 \quad \text{and} \quad i = j,$$

$$\sinh mz_j \\ \sinh z_j \end{cases} \quad \text{when} \quad |\lambda_j / (2\omega_j)| \geq 1 \quad \text{and} \quad i = j,$$

$$= 0 \quad \text{for} \quad i \neq j.$$ 

Therefore, if $|\lambda_j / (2\omega_j)| > 1$, each $\xi_{js}$ has good relative accuracy. However, if $z_1 > z_p$, then $\xi_{1s}$ may become very large relative to $\xi_{p,s}$; and since $\xi_s = Q \xi_s$, $\xi_{p,s}$ will be lost in rounding.

We now apply the above results to Poisson’s equation with Dirichlet boundary conditions. For the five-point difference operator with mesh width $\Delta x$ in the $x$-direction and $\Delta y$ in the $y$-direction, we have

$$\lambda_j = -2 \left[ 1 + \rho^2 \left( 1 - \cos \frac{j\pi}{p+1} \right) \right], \quad \omega_j = 1$$

and

$$\rho = \Delta x / \Delta y \quad \text{or} \quad \Delta y / \Delta x,$$

depending on how one orders the equations. By inspection

$$|\lambda_j / (2\omega_j)| > 1$$

for all $j$, and hence, as $s$ increases, (10.1) leads to a numerically unstable algorithm. A similar result holds for the nine-point difference approximation to Poisson’s equation.

Although the above results were obtained under the assumption of (10.1), similar results will be obtained regardless of how $A^{(r)} y_j^{(r)}$ is computed. The problem is that $A^{(r)}$ becomes very ill-conditioned as $r$ increases. For the five-point approximation, the ratio of the largest eigenvalue of $A^{(r)}$ to its smallest eigenvalue is

$$\frac{\omega_j^{2r} \cosh (2^r z_n)}{\omega_j^{2r} \cosh (2^r z_1)} \approx e^{2r(z_n - z_1)}.$$ 

Give $t$ digits of base $\beta$ arithmetic, it will generally be impossible to represent $\xi_{12}$. in $t$ digits whenever

$$2t(z_n - z_1) \geq t \ln \beta.$$ 

As noted in §3, Hockney [2], [9] has combined one or more steps of odd–even reduction with the fast Fourier transform to produce a Poisson solver. The above analysis allows one to determine the number of reductions that can be safely performed, and careful attention must be given to it.

11. The Buneman algorithm and variants. In this section, we shall describe in detail the Buneman algorithm [2] and a variation of it. The difference between the Buneman algorithm and the CORF algorithm lies in the way the right-hand side is calculated at each stage of the reduction. Henceforth, we shall assume that, in the system of (2.5), $T = I_p$, the identity matrix of order $p$. 

Again consider the system of equations as given by (2.5) with \( q = 2^{k+1} - 1 \).
After one stage of cyclic reduction, we have
\[
(11.1) \quad x_{j-2} + (2I_p - A^2)x_j + x_{j+2} = y_{j-1} + y_{j+1} - Ay_j
\]
for \( j = 2, 4, \ldots, q - 1 \), with \( x_0 = x_{q+1} = 0 \), the null vector. Note that the right-hand side of (11.1) may be written as
\[
(11.2) \quad y_j^{(1)} = y_{j-1} + y_{j+1} - Ay_j = A^{(1)}A^{-1}y_j + y_{j-1} + y_{j+1} - 2A^{-1}y_j,
\]
where \( A^{(1)} = (2I_p - A^2) \).
Let us define
\[
p_j^{(1)} = A^{-1}y_j, \quad q_j^{(1)} = y_{j-1} + y_{j+1} - 2p_j^{(1)}.
\]
Then
\[
(11.3) \quad y_j^{(1)} = A^{(1)}p_j^{(1)} + q_j^{(1)}.
\]
After \( r \) reductions, we have, by (3.3),
\[
(11.4) \quad y_j^{(r+1)} = (y_j^{(r)}}{-2r} + y_j^{(r)}}{+2r}) - A^{(r)}y_j^{(r)}.
\]
Let us write in a fashion similar to (11.3),
\[
(11.5) \quad y_j^{(r)} = A^{(r)}p_j^{(r)} + q_j^{(r)}.
\]
Substituting (11.5) into (11.4) and making use of the identity \( (A^{(r)})^2 = 2I_p - A^{(r+1)} \) from (3.3), we have the following relationships:
\[
(11.6a) \quad p_j^{(r+1)} = p_j^{(r)} - (A^{(r)})^{-1}(p_j^{(r)}}{-2r} + p_j^{(r)}}{+2r} - q_j^{(r)}),
\]
\[
(11.6b) \quad q_j^{(r+1)} = q_j^{(r)}}{-2r} + q_j^{(r)}}{+2r} - 2p_j^{(r+1)}
\]
for \( j = 2^{r+1}, i = 1, 2, \ldots, 2^k - r - 1 \), with
\[
p_0^{(r)} = p_2^{(r)} = q_0^{(r)} = q_2^{(r)} = 0.
\]
To compute \((A^{(r)})^{-1}(p_j^{(r)}}{-2r} + p_j^{(r)}}{+2r} - q_j^{(r)}\) in (11.6a), we solve the system of equations
\[
A^{(r)}(p_j^{(r)} - p_j^{(r+1)}) = p_j^{(r)}}{-2r} + p_j^{(r)}}{+2r} - q_j^{(r)},
\]
where \( A^{(r)} \) is given by the factorization (3.10), namely,
\[
A^{(r)} = -\prod_{j=1}^{2r} (A + 2 \cos \theta_j^{(r)}I_p),
\]
\[
\theta_j^{(r)} = (2j - 1)\pi/2^{r+1}.
\]
After \( k \) reductions, one has the equation
\[
A^{(k)}x_{2^k} = A^{(k)}p_{2^k}^{(k)} + q_{2^k}^{(k)},
\]
and hence
\[
x_{2^k} = p_{2^k}^{(k)} + (A^{(k)})^{-1}q_{2^k}^{(k)}.
\]
Again one uses the factorization of $A^{(k)}$ for computing $(A^{(k)})^{-1}q^{(k)}_{2^k}$. To back-solve, we use the relationship

$$x_{j-2^r} + A^{(r)}x_j + x_{j+2^r} = A^{(r)}p^{(r)}_j + q^{(r)}_j$$

for $j = i2^r$, $i = 1, 2, \ldots, 2^{k+1-r} - 1$, with $x_0 = x_{2^{k+1}} = 0$.

For $j = 2^r, 32^r, \ldots, 2^{k+1} - 2^r$, we solve the system of equations

$$(11.7) \quad A^{(r)}(x_j - p^{(r)}_j) = q^{(r)}_j - (x_{j-2^r} + x_{j+2^r})$$

using the factorization of $A^{(r)}$; hence

$$(11.8) \quad x_j = p^{(r)}_j + (x_j - p^{(r)}_j).$$

Thus the Buneman algorithm (variant 1) proceeds as follows:

(i) Compute the sequence $\{p^{(r)}_j, q^{(r)}_j\}$ by (11.6) for $r = 1, \ldots, k$, with $p^{(0)}_j = \emptyset$ for $j = 0, \ldots, 2^{k+1}$, and $q^{(0)}_j = y_j$ for $j = 1, 2, \ldots, 2^{k+1} - 1$.

(ii) Back-solve for $x_j$ using (11.7) and (11.8).

It is possible to eliminate the sequence $\{p^{(r)}_j\}$. From (11.6b) we note that

$$(11.9) \quad p^{(r+1)}_j = \frac{1}{2}(q^{(r+1)}_{j-2h} + q^{(r+1)}_{j+2h} - q^{(r+1)}_{j+2h})$$

where

$$h = 2^{r-1}.$$

Using (11.9) in (11.6a) and modifying the subscripts and superscripts appropriately, we have

$$q^{(r+1)}_j = q^{(r+1)}_{j-2h} - q^{(r+1)}_{j-h} + q^{(r+1)}_{j+h} + q^{(r+1)}_{j+2h}$$

$$(11.10) \quad + (A^{(r)})^{-1}[q^{(r+1)}_{j-3h} - q^{(r+1)}_{j-2h} + q^{(r+1)}_{j-h} - 2q^{(r+1)}_j$$

$$+ q^{(r+1)}_{j+h} - q^{(r+1)}_{j+2h} + q^{(r+1)}_{j+3h}]$$

for $j = 2^r, 2^{r+1}, \ldots, 2^{k+1} - 2^r$, with

$$q^{(r)}_0 = q^{(r)}_{2^{k+1}+1} = \emptyset$$

for all $r$.

$$q^{(j)}_j = y_j$$

for $j = 1, 2, \ldots, 2^{k+1} - 1$,

$$q^{(1)}_j = y_{j-1} + y_{j+1} - 2A^{-1}y_j$$

for $j = 2, 4, \ldots, 2^{k+1} - 2$.

To solve for $x_j$, we use the relationships (11.7) and (11.9), so that

$$(11.11) \quad x_j = \frac{1}{2}(q^{(r+1)}_{j-2h} + q^{(r+1)}_{j+h} - q^{(r+1)}_j$$

$$- (A^{(r)})^{-1}(x_{j-2h} + x_{j+2h} - q^{(r)}_j).$$

Thus the Buneman algorithm (variant 2) proceeds as follows:

(i) Compute the sequence $\{q^{(r)}_j\}$ by (11.10) for $r = 1, 2, \ldots, k$.

(ii) Back-solve for $x_j$ using (11.11).

Note that the Buneman algorithm (variant 2) requires half the storage that the Buneman algorithm (variant 1) requires. However, the variant 2 algorithm requires approximately twice as many additions.
The \( p_j \)'s and \( q_j \)'s can be written in terms of the \( x_j \)'s. In §13, we shall show how this affects the stability of the methods. Note that

\[
p_j^{(1)} = A^{-1} y_j = x_j + A^{-1} (x_{j-1} + x_{j+1})
\]

and

\[
q_j^{(1)} = y_{j-1} + y_{j+1} - 2p_j^{(1)} = x_{j-2} - (A^{-1} A^{(1)}) (x_{j-1} + x_{j+1}) + x_{j+2}.
\]

By an inductive argument, it is possible to show that

\[
p^{(r)}_j = x_j + (-1)^{r+1} S^{(r)} \left\{ 2^{r-1} \sum_{k=1}^{2^{r-1}} (x_{j-(2k-1)} + x_{j+(2k-1)}) \right\}
\]

and

\[
q^{(r)}_j = x_{j-2^r} + (-1)^r S^{(r)} A^{(r)} \left\{ 2^{r-1} \sum_{k=1}^{2^{r-1}} (x_{j-(2k-1)} + x_{j+(2k-1)}) \right\} + x_{j+2^r},
\]

where

\[
S^{(r)} = (A^{(r-1)} A^{(r-2)} \cdots A^{(0)})^{-1}.
\]

**12. Applications of the Buneman algorithm to Poisson's equation.** As was pointed out in §4, matrices of the form of (2.5) arise in solving the five-point finite difference approximation to Poisson's equation over a rectangular region with Dirichlet boundary conditions; hence, it is possible to use the methods of §11. For the five-point approximation to Poisson's equation over a rectangular region with Neumann or periodic conditions it is necessary to modify the Buneman algorithms.

For the Neumann boundary conditions, we have the system of equations

\[
\begin{align*}
Ax_0 + 2x_1 &= y_0, \\
x_{j-1} + Ax_j + x_{j+1} &= y_j, \quad j = 1, 2, \cdots, m - 1, \\
2x_{m-1} + Ax_m &= y_m, \quad \text{with } m = 2^{k+1}.
\end{align*}
\]

We define

\[
y^{(1)}_j = A^{(1)} p^{(1)}_j + q^{(1)}_j \quad \text{for } j = 0, 2, 4, \cdots, 2^{k+1},
\]

where

\[
\begin{align*}
p^{(1)}_0 &= A^{-1} y_0, \quad q^{(1)}_0 = 2(y_1 - p^{(1)}_0), \\
p^{(1)}_j &= A^{-1} y_j, \quad q^{(1)}_j = y_{j-1} + y_{j+1} - 2p^{(1)}_j, \\
&\quad j = 2, 4, \cdots, m - 2, \\
p^{(1)}_m &= A^{-1} y_m, \quad q^{(1)}_m = 2(y_{m-1} - p^{(1)}_m).
\end{align*}
\]

In general then, as in §11, we have for \( r = 1, 2, \cdots, k - 1, \)

\[
y^{(r+1)}_j = A^{(r+1)} p^{(r+1)}_j + q^{(r+1)}_j,
\]
where
\[ p_0^{(r+1)} = p_0^{(r)} - (A^{(r)})^{-1}(2p_2^{(r)} - q_0^{(r)}), \]
\[ q_0^{(r+1)} = 2(q_2^{(r)} - p_0^{(r+1)}), \]
\[ p_j^{(r+1)} = p_j^{(r)} - (A^{(r)})^{-1}(p_0^{(r)} - p_2^{(r)} - q_2^{(r)}), \]
\[ q_j^{(r+1)} = q_j^{(r)} + q_2^{(r)} - 2p_j^{(r+1)}, \]
for \( j = i2^{r+1}, \ i = 1, 2, \ldots, 2^k - r - 1. \)
\[ p_m^{(r+1)} = p_m^{(r)} - (A^{(r)})^{-1}(2p_m^{(r)} - q_m^{(r)}), \]
\[ q_m^{(r+1)} = 2q_m^{(r)} - 2p_m^{(r+1)}. \]

Finally
\[ (12.1) \]
\[ y_{2^k}^{(k+1)} = B^{(k+1)}p_{2^k}^{(k+1)} + q_{2^k}^{(k+1)}, \]
where
\[ B^{(k+1)} = 4I - (A^{(k)})^2, \]
\[ (12.2) \]
\[ p_{2^k}^{(k+1)} = p_{2^k}^{(k)} - (A^{(k)})^{-1}(p_0^{(k)} + p_{2^k+1}^{(k)} - q_{2^k}^{(k)}), \]
\[ q_{2^k}^{(k+1)} = q_0^{(k)} + q_{2^k+1}^{(k)} - 4p_{2^k}^{(k+1)}. \]

From (5.4), we see that
\[ B^{(k+1)}x_{2^k} = B^{(k+1)}p_{2^k}^{(k+1)} + q_{2^k}^{(k+1)}, \]
so that
\[ x_{2^k} = p_{2^k}^{(k+1)} + (B^{(k+1)})^{-1}q_{2^k}^{(k+1)}. \]

\( (B^{(k+1)})^{-1}q_{2^k}^{(k+1)} \) indicates a solution to the singular system \( B^{(k+1)}(x_{2^k} - p_{2^k}^{(k+1)}) = q_{2^k}^{(k+1)}. \) The factorization of \( B^{(k+1)} \) is given by (5.6). The back-substitution process proceeds as in § 11. It is also possible to eliminate the \( p_j^{(r)} \) sequence as was done in the previous section.

For periodic boundary conditions, we have the system of equations
\[ Ax_1 + x_2 + x_m = y_1, \]
\[ x_{j-1} + Ax_j + x_{j+1} = y_j \quad \text{for } j = 2, 3, \ldots, m - 1, \]
\[ x_1 + x_{m-1} + Ax_m = y_m. \]

We define
\[ y_j^{(1)} = A^{(1)}p_j^{(1)} + q_j^{(1)} \quad \text{for } j = 2, 4, \ldots, 2^{k+1}, \]
where
\[ p_2^{(1)} = A^{-1}y_2, \quad q_2^{(1)} = y_1 + y_3 - 2p_2^{(1)}, \]
\[ p_j^{(1)} = A^{-1}y_j, \quad q_j^{(1)} = y_{j-1} + y_{j+1} - 2p_j^{(1)}, \quad j = 4, 6, \ldots, m - 2, \]
\[ p_m^{(1)} = A^{-1}y_m, \quad q_m^{(1)} = y_1 + y_{m-1} - 2p_m^{(1)}. \]

In general, for \( r = 1, 2, \ldots, k - 1, \)
\[ y_j^{(r+1)} = A^{(r+1)}p_j^{(r+1)} + q_j^{(r+1)} \quad \text{for } j = i2^{r+1}, \ i = 1, 2, \ldots, 2^k - r. \]
ON DIRECT METHODS FOR SOLVING POISSON'S EQUATIONS

where

\[ p_{2x+1} = p_{2x+1}^{(r)} - (A^{(r)})^{-1}(p_{2x}^{(r)} + p_{2x+2}^{(r)} - q_{2x+1}^{(r)}) , \]

\[ q_{2x+1} = q_{2x}^{(r)} + q_{2x+2}^{(r)} - 2p_{2x+1}^{(r)} , \]

\[ p_{2x}^{(r+1)} = p_{2x}^{(r)} - (A^{(r)})^{-1}(p_{2x-2}^{(r)} + p_{2x+2}^{(r)} - q_{2x}^{(r)}), \]

\[ q_{2x}^{(r+1)} = q_{2x-2}^{(r)} + q_{2x+2}^{(r)} - 2p_{2x}^{(r+1)}, \]

\[ p_{m}^{(r+1)} = p_{m}^{(r)} - (A^{(r)})^{-1}(p_{m-2}^{(r)} + p_{m+2}^{(r)} - q_{m}^{(r)}), \]

\[ q_{m}^{(r+1)} = q_{m-2}^{(r)} + q_{m+2}^{(r)} - 2p_{m}^{(r+1)}. \]

Finally, as (12.1),

\[ y_{2x}^{(k+1)} = B_{2x}^{(k+1)} p_{2x}^{(k+1)} + q_{2x}^{(k+1)}, \]

where

\[ p_{2x}^{(k+1)} = p_{2x}^{(k)} - (A^{(k)})^{-1}(2p_{2x-1}^{(k)} - q_{2x}^{(k)}), \quad q_{2x}^{(k+1)} = 2q_{2x-1}^{(k)} - 4p_{2x}^{(k+1)} \]

and \( B_{a}^{(k+1)} \) is defined by (12.2). Then

\[ B_{2x}^{(k+1)} x_{2x} = B_{2x}^{(k+1)} p_{2x}^{(k+1)} + q_{2x}^{(k+1)}, \]

so that

\[ x_{2x} = p_{2x}^{(k+1)} + (B_{a}^{(k+1)})^{-1} q_{2x}^{(k+1)}. \]

The back-substitution process proceeds as in § 11.

It is possible to express \( p_{j}^{(r)} \) and \( q_{j}^{(r)} \) in terms of \( x_{j} \) as in (11.12) and (11.13).

13. Accuracy of the Buneman algorithms. As was shown in § 11, the Buneman algorithms consist of generating the sequence of vectors \( \{ p_{j}^{(r)}, q_{j}^{(r)} \} \). Let us write, using (11.12) and (11.13),

\[ p_{j}^{(r)} = x_{j}^{(r)} + g_{j}^{(r)}, \]

\[ q_{j}^{(r)} = x_{j-2r} + x_{j+2r} - A^{(r)} g_{j}^{(r)}, \]

where

\[ g_{j}^{(r)} = (-1)^{r+1} S^{(r)} \left\{ \sum_{k=1}^{2r-1} (x_{j-(2k-1)} + x_{j+(2k-1)}) \right\} , \]

and

\[ S^{(r)} = (A^{(r-1)} \cdots A^{(0)})^{-1} . \]

Then

\[ \| p_{j}^{(r)} - x_{j}^{(r)} \|_{2} \leq \| S^{(r)} \|_{2} \| x \|', \]

\[ \| q_{j}^{(r)} - (x_{j-2r} + x_{j+2r}) \|_{2} \leq \| S^{(r)} A^{(r)} \|_{2} \| x \|', \]

where

\[ \| v \|_{2} \] indicates the Euclidean norm of a vector \( v \),
\[ \| C \|_{2} \] indicates the spectral norm of a matrix \( C \), and
\[ \| x \|' = \sum_{j=1}^{q} \| x_{j} \|_{2}. \]
When $T = I_p$, we may redefine the polynomials given in § 3 in the following way. Let

$$\psi = -a/2,$$

and define

$$\psi = \begin{cases} 
\cos \theta & \text{for } |\psi| \leq 1, \\
\cosh \theta & \text{for } |\psi| \geq 1.
\end{cases}$$

Then in a similar fashion to (10.8),

$$p_{2n}(a) = \begin{cases} 
-2 \cos (2^n \cos^{-1} \psi) & \text{for } |\psi| \leq 1, \\
-2 \cosh (2^n \cosh^{-1} \psi) & \text{for } |\psi| \geq 1.
\end{cases}$$

Thus for $A = A^T$,

$$\|S^{(r)}\|_2 \leq \prod_{j=0}^{r-1} \|(A^{(j)})^{-1}\|_2$$

$$\leq \prod_{j=0}^{r-1} \max_{\lambda_i} |[p_{2n}(\lambda_i)]^{-1}|,$$

where $\{\lambda_i\}$ are the eigenvalues of $A$. Therefore, for $|\lambda_i| \geq 2$,

$$\|S^{(r)}\|_2 \leq 2^{-r} \prod_{j=0}^{r-1} \max_{\theta_i} \cosh 2\theta_i - 1,$$

where

$$\theta_i = \cosh^{-1}(-\lambda_i/2).$$

Finally,

$$\|S^{(r)}A^{(r)}\|_2 \leq 2^{-r+1} \max_{\theta_i} \left\{ \left( \prod_{j=0}^{r-1} \cosh 2\theta_i - 1 \right) \cosh 2\theta_i \right\}$$

when $|\lambda_i| \geq 2$.

For the five-point difference approximation to Poisson’s equation over a rectangular region with Dirichlet boundary conditions,

$$\lambda_i = -2 \left( 1 + \rho^2 \left( 1 - \cos \frac{i\pi}{p+1} \right) \right),$$

where $\rho = \Delta x/\Delta y$ or $\Delta y/\Delta x$ depending on the ordering of the equations. Thus

$$\theta_i = \cosh^{-1} \left( 1 + \rho^2 \left( 1 - \cos \frac{i\pi}{p+1} \right) \right),$$

which implies $\theta_i > 1$ for all $i$. Then

$$\max_{\theta_i} \left[ \cosh 2\theta_i \right]^{-1} = \left[ \cosh 2 \left( \cosh^{-1} \left( 1 + \rho^2 \left( 1 - \cos \frac{i\pi}{p+1} \right) \right) \right) \right]^{-1}. $$
Thus, after some simplification,

\[(13.6) \quad \| S^{(r)} \|_2 \leq \prod_{j=0}^k \frac{e^{-c_r \theta_1}}{1 + e^{-2j+1 \theta_1}} \leq e^{-c_r \theta_1}, \]

where \( c_r = 2^r - 1 \), \( \cosh \theta_i = 1 + \rho^2 \left( 1 - \cos \frac{\pi}{p+1} \right) \).

A similar calculation shows that

\[(13.7) \quad \| A^{(r)} S^{(r)} \|_2 < 2e^{\theta_r}. \]

Therefore, from (13.6), we see that for large \( r \), \( p^{(r)} \) will be a good approximation to \( x_j \). And from (13.5) and (13.7), we see that

\[ \| q^{(r)}_j - (x_{j-2^r} + x_{j+2^r}) \|_2 \leq 2e^{\theta_r} \| x \|_r, \]

so that the \( \| q^{(r)}_j \|_2 \) remains bounded throughout the calculation. This explains why the Buneman algorithms lead to numerically stable results for solving the finite difference approximation to Poisson’s equation.

14. Conclusion. Numerous applications require the repeated solution of a Poisson equation. The operation counts given by Dorr [5] indicate that the methods we have discussed should offer significant economies over older techniques; this has been verified in practice by many users. Computational experiments comparing the Buneman algorithm (variant one), the MD algorithm, the Peaceman–Rachford alternating direction algorithm and the point successive over-relaxation algorithm are given by Buzbee, et al. [3]. We conclude that the method of matrix decomposition, the Buneman algorithms, and Hockney’s algorithm (when used with care) are valuable methods.

Acknowledgment. This paper has benefited greatly from the comments of Dr. F. Dorr, Mr. J. Alan George, Dr. R. Hockney and Professor O. Widlund.
